AB Reportedly, bacterial DNA containing unmethylated cytosine-guanosine dinucleotide motif-containing oligodeoxynucleotides (CpG-ODNs) can induce Th1-type adjuvant effects. The authors produced autoantibodies and induced hepatitis in mice using extracted proteins from human hepatocytes with CpG-ODNs as adjuvant. Western blot anal. was performed of sera from immunized mice and two patients with autoimmune hepatitis (AIH). When a common band was detected, N-terminal amino acid sequencing was performed to determine its site. For detection of antibodies against the identified protein (calreticulin), ELISA was performed of sera of 50 patients with AIH: 45 with primary biliary cirrhosis (PBC), 24 with chronic hepatitis C (CH), and 24 healthy controls. Mice were immunized with calreticulin protein with CpG-ODNs as adjuvant. Several reacted bands were detected in their sera; in addition, a common band to the sera of patients with AIH was detected at 60 kDa. Subsequent N-terminal amino acid sequencing revealed that the protein was human calreticulin. ELISA showed that, of patients with AIH, PBC, and CH, 30.0% (15/50), 17.8% (8/45), and 12.5% (3/24), resp., were pos. for anti-calreticulin antibodies. Splenocytes from immunized mice produced IFN-γ after they were pulsed with calreticulin protein. Histol. analyses of liver specimens taken from mice immunized with calreticulin protein together with CpG-ODNs showed spotty and focal necrosis. Immunofluorescence anal. showed increased expression of calreticulin in the liver treated with CpG-ODNs. These results suggest that a breakthrough of immune self-tolerance to calreticulin is induced with CpG-ODNs as adjuvant and that calreticulin protein might be a target antigen in this model.

AB Inhibitory oligodeoxynucleotides (ODNs), which are capable of blocking CpG-induced inflammation, have been anticipated to be beneficial therapeutic agents for autoimmune diseases. In this study, we show that GpC ODN, which inverted the cytosine guanine sequence of CpG motif to guanine cytosine sequence, is an inhibitory ODN. The inhibitory effects of GpC ODN on CpG ODN-induced immune activation were confirmed by cytokine assay using splenocytes from lupus-prone MRL-lpr/lpr mice. In vivo, injecting MRL-lpr/lpr mice with GpC ODN did not reduce the deposition of IgG and C3 in the glomeruli, the serum level of IL-12, the serum level of rheumatoid factors and anti-ds DNA antibody, or alter the composition of IgG isotypes of anti-ds DNA antibody. However, the mice in the GpC group showed less proteinuria, significantly lower blood urea nitrogen levels (BUN) and significantly prolonged survival. The results suggest that inhibitory ODNs, such as GpC ODN, have the potential to become a treatment for autoimmune diseases, like lupus nephritis.

AB Objective: To investigate the effects of an intradermal injection of oligodeoxynucleotides (ODNs) containing unmethylated CpG motifs on Con A-induced hepatitis, an exptl. model of immune-mediated hepatitis. Methods: Con A was injected i.v. into Balb/c mice. Twelve hours after Con A challenge, blood and liver samples were obtained. CpG ODN was injected intradermally 48 h before Con A challenge. The extent of liver injury was assessed by determining serum alanine transaminase (ALT) and by liver histol. Serum levels of cytokines, including interferon (IFN)-γ, tumor necrosis factor (TNF)-α, interleukin (IL)-4 and IL-5, were measured by ELISA. Results: Co-administration of Con A and CpG ODN significantly increased serum ALT in mice compared with that in the case of administration of Con A alone (10,268±4,654 and 1,140±832 IU/l, resp., $p<0.05$). In liver histol., mice treated with CpG ODN and Con A showed more extensive midzonal necrosis than did mice treated with Con A alone. These mice also showed significant increases in serum TNF-α and IFN-γ and decrease in serum IL-5. Conclusions: The results indicate that CpG ODNs aggravate Con A-induced hepatitis by stimulating the production of T-helper-1 (Th1) cytokines, TNF-α and IFN-γ, suggesting that bacterial DNA that contains unmethylated CpG motifs may contribute to the exacerbation of immune-mediated liver injury.

AB Purpose: To investigate a new modality of mucosal vaccines, we evaluated the effectiveness of intragastric immunization for inducing a mucosal immune response in the gastrointestinal tract. Methods: Mice were immunized with β-galactosidase (β-gal) and synthesized oligodeoxynucleotides containing a CpG motif (CpG-DNA) by intragastric injection, and the immune response was compared with those induced by 3 other immunization forms: intranasal, oral, and intradermal. Results: Intragastric immunization with β-gal and CpG-DNA induced significant anti-β-gal fecal IgA production at 2 wk; however, at 4 wk the response was lacking. In contrast, intranasal immunization with β-gal and CpG-DNA induced the highest anti-β-gal fecal IgA production at 4 wk. Conclusion: Although intragastric immunization with protein and CpG-DNA induces a mucosal immune response in the gastrointestinal tract, intranasal immunization is the most effective to induce both mucosal and systemic immune responses. This finding may increase the possibility for developing vaccines against mucosal pathogens, especially Helicobacter pylori.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB Polynucleotides capable of effectively suppressing the immunoactivity attributed to DNA having a CpG motif, to thereby find application in the prevention and/or treatment of immunol. diseases such as arthritis, are provided. In particular, polynucleotides comprising a CpG motif having a methylated guanine, and a pharmaceutical composition comprising the polynucleotide, are provided. To investigate the effects of an intradermal injection of an methylated oligodeoxynucleotide (ODN) containing CpG motifs on the severity of collagen-induced arthritis (CIA), methylated ODN containing a CpG motif was injected intradermally into DBA/1 LacJ mice at a dosage of 20 μg (yielding CpmG-CIA mice) 1 wk prior to the first immunization with bovine type II collagen (CII). CpmG-CIA mice had significantly lower arthritis scores than CIA mice or CpG-CIA mice. CpmG-CIA mice had less severe histopathol. changes than CIA mice and CpG-CIA mice. Moreover, splenocytes in CpG-CIA mice produced higher IFNγ titers in response to CII than did splenocytes in CIA mice and mCpG-CIA mice. Injection of methylated oligo-DNA containing CpG motifs alleviated CIA through activation of the Th1-type immune response, suggesting that microbial infection could be one of the mechanisms for aggravation or exacerbation of arthritis or, alternatively, that such infection could be an adjuvant in the induction of arthritis in rheumatoid arthritis. Moreover, administration of methylated CpG ODN to mouse bone marrow-derived macrophages suppressed IL-6 and IL-12 production

AB Macrolide antibiotics have unique immunomodulatory actions apart from their antimicrobial properties. The authors examined the effect of erythromycin (EM), a 14-member macrolide, on the immune response to a DNA vaccine that induces a T-helper-1 (Th1)-biased immune response through a Th1-promoting adjuvant effect of unmethylated CpG motifs within plasmid DNA. EM enhanced Th1 responses in plasmid DNA-immunized mice as measured by antigen-specific IgG2a antibody production, interferon-γ production by antigen-specific CD4+ T cells, and cytotoxic T lymphocyte responses. EM augmented the accessory cell activity of unmethylated CpG DNA-stimulated antigen-presenting cells (APCs), suggesting that EM enhances Th1 responses to a DNA vaccine, possibly through augmentation of accessory cell activity of APCs stimulated with CpG motifs within plasmid DNA. (c) 1999 Academic Press.

AB A series of 21 phosphodiester oligodeoxyribonucleotides containing the core sequence 5'-GACGTT-3' or related control sequences were prepared and tested for their immunostimulatory effect on murine macrophages. The range of

structural modifications tested included substituents at 3'- or 5'-termini, N3-methylation of thymidine residues, and hexaethylene glycol linkers favoring nicked or cyclic dumbbell duplexes. Lipophilic and cationic substituents at the termini failed to increase the release of TNF-α and nitric oxide, but two new types of modification were found that enhance the stimulation of RAW264.7 macrophages. One is the substitution of the 5'-terminal hydroxyl group with an amino group, and the other is the introduction of linkers favoring nicked duplexes. Even for sequences without linkers, UV-melting anal. and two-dimensional NMR showed that the core sequence 5'-GACGTT-3' readily forms a duplex. The cyclic derivative of the most active nicked dumbbell sequence is inactive, however. Together these results suggest a recognition of both the 5'-terminus and the core of the CpG oligonucleotides by the putative receptor(s) and provide an entry into a class of modified oligonucleotides whose activity rivals that of phosphorothioates, but consists of synthetic compds. that are single stereoisomers.

AB The (2-cyano-1-phenylethoxy)carbonyl (2clpeoc) group was developed as a new base-labile protecting group for the 5'-OH function in solid-phase synthesis of oligoribonucleotides via the phosphoramidite approach. The half-lives of its β-elimination process by 0.1M DBU (1,8-diazabicyclo[5.4.0]undec-7-ene) were determined to be 7-14 s by HPLC investigations. The 2'-OH function was protected with the acid-labile tetrahydro-4-methoxy-2H-pyran-4-yl (thmp) group, while the 2-(4-nitrophenyl)ethyl (npe) and 2-(4-nitrophenyl)ethoxycarmonomeric building blocks, both phosphoramidites and nucleoside-functionalized supports, as well as the build-up of oligoribonucleotides by means of this approach are described.

AB Undesired N7 platination of 2'-deoxyguanosine residues at predetd. sites in an oligodeoxynucleotide (ODN) sequence is prevented by applying the sterically demanding diphenylcarbamoyl (DPC) as an O6-protecting group. The presence of a base-labile oxalyl linker between the immobilized 3'-nucleotide and controlled pore glass (CPG) allows cleavage of the protected ODN from the support and leaves DPC protection unaffected. This method provides an ODN with specifically blocked guanine-N7 sites for platination. In the hexanucleotides prepared in this study, 5'-GGBGGT-3' (for B = T, C and A), a platinum GG adduct is introduced at G4,G5. These site-specific platinated hexamers were isolated in a yield of 65%, and were fully characterized by using reversed-phase HPLC (high performance liquid chromotog.), LCMS (liquid chromatog.-mass spectrometry), MALDI-TOF MS (matrix-assisted laser desorption/ionization time-of-flight mass spectrometry), PAGE and Maxam-Gilbert sequencing anal.

AB The synthesis of mixed MeSATE-phosphotriester and -phosphodiester prooligonucleotides [MeSATE = 2-(acetylthio)ethyl] of various sequences is described. The strategy is based on the use of allyloxycarbonyl (AOC) protection for nucleobases and MeSATE and allyl (All) protection for internucleosidic phosphates, in combination with palladium(0) deprotection. The synthesis was achieved by the use of phosphoramidite chemical on a photolabile solid support, enabling MALDI-TOF mass spectrometric anal. to be performed on the still anchored prooligonucleotides.

AB The utility of various kinds of acid salts of azole derivs. as promoters for the condensation of a nucleoside phosphoramidite and a nucleoside is investigated. Among the salts, N-(phenyl)imidazolium triflate, N-(p-acetylphenyl)imidazolium triflate, N-(methyl)benzimidazolium triflate, benzimidazolium triflate, and N-(phenyl)imidazolium perchlorate have shown extremely high reactivity in a liquid phase. These reagents serve as powerful activators of deoxyribonucleoside 3'-(allyl N,N-diisopropylphosphoramidite)s or 3'-(2-cyanoethyl N,N-diisopropylphosphoramidite)s employed in the preparation of deoxyribonucleotides, and 3'-O-(tert-butyldimethylsilyl)ribonucleoside 2'-(N,N-diisopropylphosphoramidite)s or 2'-O-(tert-butyldimethylsilyl)ribonucleoside 3'-(N,N-diisopropylphosphoramidite)s used for the formation of 2'-5' and 3'-5' internucleotide linkages between ribonucleosides, resp. The azolium salt has allowed smooth and high-yield condensation of the nucleoside phosphoramidite and a 5'-O-free nucleoside, in which equimolar amts. of the reactants and the promoter are employed in the presence of powdery mol. sieves 3A in acetonitrile. It has been shown that some azolium salts serve as excellent promoters in the solid-phase synthesis of oligodeoxyribonucleotides and oligoribonucleotides. For example, benzimidazolium triflate and N-(phenyl)imidazolium triflate can be used as

effective promoters in the synthesis of an oligodeoxyribonucleotide, 5'CGACACCCAATTCTGAAAAT3' (20mer), via a method using O-allyl/N-allyloxycarbonyl-protected deoxyribonucleoside 3'-phosphoramidites or O-(2-cyanoethyl)/N-phenoxyacetyl-protected deoxyribonucleotide 3'-phosphoramidite as building blocks, resp., on high-cross-linked polystyrene resins. Further, N-(phenyl)imidazolium triflate is useful for the solid-phase synthesis of oligoribonucleotides, such as 5'AGCUACGUGACUACUACUUU3' (20mer), according to an allyl/allyloxycarbonyl-protected strategy. The utility of the azolium promoter has been also demonstrated in the liquid-phase synthesis of some biol. important substances, such as cytidine-5'-monophospho-N-acetylneuraminic acid (CMP-Neu5Ac) and adenylyl(2'-5')adenylyl(2'-5')adenosine (2-5A core).

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB In general, the invention features the use of novel protection schemes and solid phase preparation reactions to generate mols. of core structure M (M is a multifunctional low mol. weight compound, such as a saccharide, amino sugar, deoxy sugar, nucleoside, nucleotide, coenzyme, amino acid, lipid, steroid, vitamin, hormone, alkaloid, or small mol. drug), which have a plurality of functionalities, each of which can be individually protected or functionalized. Thus, d(TTTT) and d(TAGCT) were prepared using an apparatus for manual preparation consisted of column type reactor fitted with a sintered glass frit, a stopcock, and a connection to a vacuum pump to remove solvents by suction or to dry the support just before the condensation step.

AB Compds. and methods for preparing oligonucleotide analogs are provided. In preferred embodiments, the methods involve solid-phase coupling of synthons bearing either 3'-electrophilic groups and 5'-nucleophilic groups or 5'-electrophilic groups and 3'-nucleophilic groups to form neutral, achiral oligomers. This process for forming covalent linkages comprises the steps of: (a) providing a support-bound synthon having structure I and (b) contacting

said support-bound synthon with a solution-phase synthon having structure II, said contacting being for a time and under reaction conditions effective to form a covalent linkage having structure CHN:RACH2, CH2CH:NRA, CH2RAN:CH, or RAN:CHCH2; wherein: Z1 and Y2 are selected such that (i) Z1 is C(O)H and Y2 is CH2RANH2; or (ii) Z1 is CH2RANH2 and Y2 is C(O)H; or (iii) Z1 is CH2C(O)H and Y2 is RANH2 ; or (iv) Z1 is RANH2 and Y2 is CH2 C(O)H; each RA is, independently, O or NR2 ; Y1 is OH, ORHP, CH2OH, or CH2ORHP where RHP is a hydroxyl protecting group; (P) is a solid support; each LC is, independently, a covalent linkage having the structure CH:NRACH2, CH2CH:NRA, CH2RAN:CH, RAN:CHCH2, OP(O)2OCH2, or OP(S)(O)OCH2; n is 0-200; each R2 is, independently, H; alkyl or substituted alkyl having 1 to about 10 carbon atoms; alkenyl or substituted alkenyl having 2 to about 10 carbon atoms; alkynyl or substituted alkynyl having 2 to about 10 carbon atoms; alkaryl, substituted alkaryl, aralkyl, or substituted aralkyl having 7 to about 14 carbon atoms; each B is, independently, a nucleosidic base; each Q is, independently, O or S; and each X is, independently, H, OH, alkyl or substituted alkyl having 1 to about 10 carbon atoms, F, Cl, Br, CN, CF3, OCF3, OCN, O-alkyl, S-alkyl, or N-alkyl. Thus, e.g., 5'-O-phthalimidothymidine was loaded onto succinyl-CPG whose free amino groups were capped [HO2C(CH2)2CONMe-CPG-NMe2] to provide 5'-O-phthalimido-3'-O-(succinyl-CPG-NMe2)thymidine; deprotection to the 5'-O-amino was followed by 10 cycles of coupling/deprotection with 5'-O-phthalimido-3'-formyl-3'-deoxythymidine and a final coupling with 5'-tert-butyldiphenylsilyl-3'-formyl-3'- deoxythymidine to provide a bound oxime-linked oligonucleoside; reduction of the latter with NaCNBH3 provided the bound aminohydroxyl-linked oligonucleoside which upon methylation with formaldehyde/NaCNBH3 provided the bound oligomer with 3'-de(oxyphosphinico)-3'-[methylene(methylimino)] 3'-CH2-NMe-O-5' backbone; oligomer was cleaved from the solid support with 30% NH3, deprotected with TBAF, and purified to provide T12 with 3'-de(oxyphosphinico)-3'-[methylene(methylimino)] backbone.

AB A novel 5'-3' directed DNA synthesis will be described. Together with addnl. investigations on model compds. a synthetic strategy is established which allows multi-selective deprotections. This offers the potential to either generate oligonucleotides in different sequence specific

protection/functionalization states or to create a combinatorial set of mols. available for specific mol. interaction or recognition expts.

AB A new efficient method for solid-phase of oligoribonucleotides via the phosphoramidite approach is described. The combination of the base-labile 2-dansylethoxycarbonyl (Dnseoc) group for 5'-OH protection with the acid-labile tetrahydro-4-methoxy-2H-pyran-4-yl(Thmp) group as 2'-OH blocking group is orthogonal regarding cleavage reactions and fulfills the requirements of an automated synthesis in an excellent manner if the phosphoramidite function carries the N,N-diethyl-O-[2-(4-nitrophenyl)ethyl]substitution.

AB Deoxyribonucleoside phosphoramidites are prepared in situ from 5'-O,N-protected deoxyribonucleosides and NCCH2CH2P[N(CHMe2)2]2 with tetrazole as catalyst, and the solns. applied directly on an automatic solid-phase DNA synthesizer. Using LCAA-CPG support and a cycle time of 12.5 min,

oligonucleotides of 16-25 bases are obtained with a dimethoxytritylation-efficiency per cycle of 98.0-99.3%. The crude and fully deblocked products are of a purity comparable to that obtained using purified phosphoramidites.

AB To compare the kinetics of their enzymic elimination from the DNA of liver, kidney, lung, and brain, the alkylation products O4-ethyl-2'-deoxythymidine (O4-EtdThd) [59495-22-6] and O6-ethyl-2'-deoxyguanosine (O6-EtdGuo) [50704-46-6] were quantitated by competitive radioimmunoassay over a period of 48 h after a single pulse of N-ethyl-N-nitrosourea (EtNU) [759-73-9] applied i.p. to 10- and 28-day-old BDIX-rats. The content of O4-EtdThd in the DNA of all organs analyzed remained stable, while O6-EtdGuo (initially formed in DNA with 3-4 times higher frequency than O4-EtdThd) was rapidly removed from the DNA of liver, followed by lung and kidney, but persisted strongly in the DNA of brain. At 48 h after the EtNU-pulse, the O4-EtdThd content of liver DNA exceeded the O6-EtdGuo content by about a factor of 4. Since O6-EtdGuo and O4-EtdThd are miscoding DNA lesions, the lack of enzymic removal of O4-EtdThd is surprising in view of the apparent concern of cells to restore the integrity of the O6-position of guanine. Genetic consequences more specifically connected with the formation of O6-alkylguanine in DNA might be considered, e.g., possible alterations of gene expression via interference with enzymic 5-cytosine methylation in 5'-CpG-3' sequences of newly replicated DNA.
